QUICKSTART

 Copy as Markdown

Quickstart

Build and deploy a full-stack Flutter and Serverpod app, hosted on the web, in 10–15 minutes. We have tested the default setup with Antigravity, Cursor, and Claude Code, but most agentic editors will work.

Prerequisites

Serverpod is tested on Mac, Windows, and Linux. Before you can install Serverpod, you need to have **Flutter** installed. Serverpod 4 requires Flutter 3.44.4 or later, which includes Dart 3.12.2.

INFO

Check your Flutter installation by running the following command in your terminal:

```
$ flutter doctor
```

Install Serverpod

Serverpod is installed using the Dart package manager. To install Serverpod, run the following command in your terminal:

```
$ dart install serverpod_cli
```

Verify the installation by running:

```
$ serverpod
```

WARNING

If a previous version of Serverpod is already installed with `dart pub global activate`, deactivate it before installing or upgrading:

```
$ dart pub global deactivate serverpod_cli
```

Create the project

Use Serverpod's `quickstart` command to create a new project.

```
$ serverpod quickstart my_project
```

The command opens an interactive screen where you select the editor or agent you plan to use. Navigate with your mouse or use the arrow keys to move around, press `Space` to select your editor, then press `Enter` to create the project.

Next, open your newly created project with your favorite AI powered editor. Open the *root* folder of the full project, for example, `my_project`, which includes the server, client, and Flutter app.

IMPORTANT

If you are using Cursor, you will need to **enable the Serverpod and Dart MCP servers** in your project settings (*Cursor Settings > Tools & MCPs*).

Start the server and the app

Start the server and the Flutter app by opening up a terminal window and running the `serverpod start` command:

```
$ serverpod start
```

After the server has started and your app has finished building, the app will open in a new browser window. Try it out by entering your name and clicking the send button.

Build your app

Instruct your AI agent to build your app. Here are a few simple prompts that you can try:

[Job board]

Build a professional job marketplace where employers post openings and manage applications, while job seekers browse listings. Use an editorial-inspired design with bold typography.

[CRM]

Build a professional job marketplace where employers post openings and manage applications, while job seekers browse listings. Use an editorial-inspired design with bold typography.

[Social network]

Build a professional job marketplace where employers post openings and manage applications, while job seekers browse listings. Use an editorial-inspired design with bold typography.

The agent will start building your app. It will manage your database and perform a hot reload when the app is complete.

TIP

If your app uses authentication, the verification code will be displayed as an alert in Serverpod's command line interface. Press the **C** key to copy the code.

TIP

If the agent fails to reload the app, you can always hit the **R** key to force a restart of the server and the app.

Deploy the app to the cloud

Deploy your web app and backend to **Serverpod Cloud**, a fully managed platform built by the Serverpod team. Your first project includes a one-month free trial, with no credit card required.

Create your Cloud account and create a project on the **Serverpod Cloud Console**. Enable the database when you create the project if your server uses one. Then launch your app:

```
$ serverpod cloud launch
```

This links your project to Cloud and deploys your backend along with the web build of your app.

After the first launch, you redeploy any changes by running `serverpod cloud launch` again.

 TIP

In the [Serverpod Cloud Console](#), open your project and use the **Logs**, **Sessions**, and **Metrics** tabs to see what your server is doing.

Get help

We welcome feedback on agent skills, MCP servers, and the `serverpod start` workflow. If you run into issues, reach out on [Discord](#) or file an issue on [GitHub](#). Pull requests are welcome.

Happy building with Serverpod 4.
