Introduction

Serverpod is an open-source full-stack framework for Flutter, built from the ground up for agentic coding. You write your entire stack in Dart, define your data models in YAML, and call your server endpoints from your Flutter app through generated, type-safe Dart code. No REST contracts to maintain, no language-switching, and no boilerplate code.

TIP

If you are a Flutter developer, check out our [Quickstart guide](#) to get up and running in minutes. If you don't have Flutter installed and just want to try things out, get started with [App Studio](#).

Build with Dart everywhere

Define an endpoint on the server:

```
class GreetingEndpoint extends Endpoint {  
  Future<String> hello(Session session, String name) async {  
    return 'Hello, $name';  
  }  
}
```

Call it from your Flutter app:

```
final greeting = await client.greeting.hello('World');  
print(greeting); // Hello, World
```

Endpoint methods on the server become typed methods in your app. Serverpod handles serialization, transport, and the code generation in between.

Who Serverpod is for

Serverpod is built for Flutter teams that want a Dart-only stack: solo developers, app agencies, startups, and small teams shipping production apps without juggling languages. If your app uses Flutter, your team already knows Dart. If you'd rather ship features than struggle with infrastructure, Serverpod is a good fit.

What's included

Serverpod covers all common backend needs out of the box:

- **Code generation:** Server endpoints and the app stay in sync automatically. Define a method on the server, call it from the app as if it were local Dart code.
- **Fast dev loop:** See your changes as you save. `serverpod start` regenerates code and hot reloads your server and app, and the `M` key creates and applies a database migration.
- **Type-safe ORM:** Query Postgres or SQLite with Dart. Filters, relations, and joins are checked at compile time. Schema changes ship as versioned migrations.
- **Client-side database:** Use the same models in your Flutter app through a generated local database, including migrations.
- **Authentication:** Built-in sign-in with Google, Apple, GitHub, Microsoft, Firebase, email/password, passkeys, and more. Anonymous and custom providers supported.
- **Real-time streams:** Stream Dart objects to your app over WebSockets without writing connection-management code.
- **Deployment:** Deploy to Serverpod Cloud, or self-host with Docker, Terraform, or your own infrastructure. No vendor lock-in.

- **Logging and monitoring:** Inspect requests, exceptions, and slow queries with [Serverpod Insights](#), the desktop app that ships with Serverpod.
- **File uploads:** Store in Amazon S3, Google Cloud Storage, or your database.
- **Task scheduling:** Schedule a method to run later with type-safe future calls. They persist across server restarts.
- **Caching:** Cache primitives and serializable models in-memory or in Redis.
- **Web server:** Serve REST APIs, webhooks, and web pages with the built-in [web server](#), based on [Relic](#).
