Overview

Once your server is written, the work shifts from building features to running them. This section covers what you need after deployment: seeing what the server is doing, proving to a host that it is healthy, securing the traffic it accepts, finding out when something breaks, scaling past a single process, and measuring it under load.

Everything here works the same whether you deploy to [Serverpod Cloud](#) or [host it yourself](#), though the two differ in how much is set up for you.

What each page covers

- **Logging**: what the server records for every call, where those records go, and how to keep the log tables from growing without bound.
- **Health checks**: the HTTP endpoints a host calls to decide whether your server is alive and ready for traffic, plus the metrics Serverpod collects about itself.
- **Security and TLS**: how traffic to your server is encrypted, and when you need to configure that yourself.
- **Exception monitoring**: reporting exceptions to a monitoring service as they happen. This one is an experimental API.
- **Scalability**: roles for scale-out, isolates for CPU work, Postgres and connection pools, Redis, JWT auth, and streaming tradeoffs.
- **Redis**: the optional service that lets several server instances share a cache, messages, and auth revocation, plus how to enable it, set its password, run it locally in Docker, and connect a GUI.
- **Load testing**: measuring how a production-like server behaves under concurrent traffic, with Locust or the generated client.

Related

- [Configuration](#): the config files and environment variables every setting on these pages is read from.
- [Sessions](#): the object that produces most of what ends up in your logs.
- [Caching](#): storing values in server memory or Redis.
- [Run code on shutdown](#): cleanup work when the server stops.
- [Insights](#): the companion app for reading logs and metrics.
