CREATE-REPAIR-MIGRATION

 Copy as Markdown

serverpod create-repair-migration

The `serverpod create-repair-migration` command builds a migration by comparing the target state to what is actually in the live database, rather than to the latest migration. Use it to bring a database back in sync when it has drifted from your migration history.

Select which database to inspect with `--mode` (`development`, `staging`, or `production`), and target a specific version with `--version`. See [Migrations](#).

Usage

Repairs the database by comparing the target state to what is in the live database instead of comparing to the latest migration.

Usage: `serverpod create-repair-migration` [arguments]

`-h, --help` Print this usage information.
`-f, --force` Creates the migration even if there are warnings or information that may be destroyed.
`-t, --tag` Add a tag to the revision to easier identify it.
`-v, --version` The target version for the repair. If not specified, the latest migration version will be repaired.
`-m, --mode` Used to specify which database configuration to use when fetching the live database definition.
 [development (default), staging, production]

Run "`serverpod help`" to see global options.
